FIRST PROJECT OF MATH544: ON CALCULUS OF VARIATIONS *February, 2013.*
Prove all theorems and lemmas in the text.

In the theory of extrema of functions of single variable, a necessary condition for a minimum, besides $f'(x) = 0$, is that $f'' \geq 0$ (if it exists). A condition somewhat analogous to this holds for functionals. Let us suppose that there is an admissible function y. for which $J(y) = \int_a^b L)x, y, y')dx$ is a minimum. Then $f(\epsilon) = J(y + \epsilon h)$ has a minimum at $\epsilon = 0$; accordingly $f'(0) = 0$ (from which follows the Euler-Lagrange equation $E_y(L) = 0$ and $f''(0) \geq 0$, assuming its existence. Hence for all all h,

$$f''(0) = \int_a^b [L_{yy}\, h^2 + 2L_{yy'}\, h\, h' + L_{y'y'}\, h'^2]dx \geq 0$$

.

Choose a special variation

$$h = \begin{cases} 0 & a \leq x \leq \xi - \epsilon \\ 1 + (x - \xi)/\epsilon & \xi - \epsilon \leq x \leq \xi \\ 1 - (x - \xi)/\epsilon & \xi \leq x \leq \xi + \epsilon \\ 0 & \xi + \epsilon \leq x \leq b \end{cases} \tag{1}$$

If we substitute this function in the above expression an let $\epsilon \to 0$, then the term

$$\frac{1}{\epsilon^2} \int_{\xi-\epsilon}^{\xi+\epsilon} L_{y'y'} dx$$

will dominate the left hand side of the above inequality and determine its sign. Thus the the sign of $L_{y'y'}$ determines the sign of $f''(0)$, and for minimum, the Legendre condition $L_{y'y'} \geq 0$ must hold. We have the Legendre test:

Theorem 1. *The Legendre test. If*
(i) Euler-Lagrange equation is satisfied,

(i) the range of integration is sufficiently small,
(iii) the sign of $L_{y'y'}$ is constant throughout this range,
then J(y) is a minimum or a maximum value of J according as the sign of $L_{y'y'}$ is positive or negative.

The second variation: Let $y = y(x)$ be the path of integration for which the integral $J(y) = \int_a^b L(x, y, y')dx$ is minimum or maximum (sometimes called the integral is stationary). Consider all admissible functions $y + \varepsilon h$ where both y and h belong to $C^2[a, b]$. Then

$$J(y + \varepsilon h) = J(y) + \frac{\varepsilon^2}{2} J_2 + O(\varepsilon^3)$$

where

$$J_2 = \int_a^b [h^2 \frac{\partial^2 L}{\partial y^2} + 2\, h\, h' \frac{\partial^2 L}{\partial y\, \partial y'} + h'^2 \frac{\partial^2 L}{\partial y'^2}]\, dx$$

If $J(y)$ is minimum (or maximum) the sign of J_2 must be positive (or negative) without depending upon the choice of $h(x)$, for all sufficiently small ε. For simplicity we use the following notation: $L_0 = \frac{\partial L}{\partial y}$, $L_1 = \frac{\partial L}{\partial y'}$. $L_{00} = \frac{\partial^2 L}{\partial y^2}$, $L_{01} = \frac{\partial L}{\partial y\, \partial y'}$, $L_{11} = \frac{\partial^2 L}{\partial y'^2}$. Then J_2 takes the form

$$J_2 = \int_a^b [L_{00}\, h^2 + 2L_{01}\, hh' + L_{11}\, h'^2]dx$$

.

We have the following Lemma. Proof is straightforward (done in the class)

Lemma 2. *Let $h(a) = h(b) = 0$, then*

$$J_2 = \int_a^b \{h^2\, (L_{00} - \frac{d}{dx} L_{01}) - h\, \frac{d}{dx}\, (h'\, L_{11})\}dx$$

.

Definition. *(Jacobi equation and Jacobi field). Let $u \in C^2[a, b]$. Then the following equation is called the Jacobi equation.*

$$\{L_{00} - \frac{d}{dx}(L_{01})\}\, u - \frac{d}{dx}(L_{11}\frac{du}{dx}) = 0$$

the function u satisfying this second order ODE is called the Jacobi field

Lemma 3. *If $h(a) = h(b) = 0$ and is a Jacobi field then*

$$J_2 = \int_a^b L_{11}\,[h' - h\,\frac{u'}{u}]^2\,dx,$$

If the term $\{h' - h\,(\frac{u'}{u})\} \neq 0$ and L_{11} has constant sign for all points of the extremal arc AB, where $A = (a, y(a))$ and $B = (b, y(b))$, then J_2 must have a sign which is independent of the choice of h. Now in the extremal case

$$J(y + \varepsilon h) - J(y) = \frac{\varepsilon^2}{2}\,J_2 + O(\varepsilon^3)$$

Hence J takes its minimum value (or maximum value) if L_{11} is positive (or negative) at all points on the extremal curve $y(x)$ with $x \in [a, b]$. This is essentially the Legendre test stated above.

If , however, L_{11}, does not keep its sign constant at all $x \in [a, b]$ on the curve $y(x)$, then the value $J(y)$ is neither a minimum nor a maximum.

If the term $\{h' - h\,(\frac{u'}{u})\}$ vanishes at all points of the extremal curve $y(x)$. Then it is clear that $h(x) = \alpha\, u(x)$, where α is an arbitrary constant. Along the extremal curve $y(x)$ the first variation vanishes. If in addition $h(x) = \alpha u(x)$ is chosen then the second variation, J_2 vanishes as well. The sign of $\delta J = J(y + \varepsilon h) - J(y)$ will depend on the third variation $\delta J = \frac{\varepsilon^3}{6}\,J_3$, where

$$J_3 = \int_a^b [h^3\,L_{000} + 3h^2 h'\,L_{001} + 3hh'^2 L_{011} + h'^3 L_{111}]dx$$

Since the sign of δJ depends on that of ε there can be no maximum or minimum value of J unless J_3 vanishes, in which case the sign of δJ will depend on that of J_4 , the fourth variation. In order to avoid this difficulty

Jacobi proposed a test. This test provides whether the $h(x) = \alpha u(x)$ at all points of the extremal curve $y(x)$.

Definition: Let $u(x)$ be a solution of the Jacobi equation. Let $u(a) = 0$. This means that the Jacobi field vanishes at the point $A = (a, y(a))$. The all other points on the extremal curve $y(x)$ at which $u(x)$ vanishes are called the *conjugate points* to the point A.

The jacobi field (a function satisfying the Jacobi equation with $u(a) = 0$) may be given as the linear sum of the fundamental solutions u_1 and u_2 of the Jacobi equation.

$$u(x) = a_1 u_1(x) + a_2 u_2(x)$$

where a_1 and a_2 are constants. Since $u(a) = 0$, then

$$\frac{u_1(a)}{u_2(a)} = -\frac{a_1}{a_2}$$

Hence if x is the abscissa of the conjugate point to A $(u(x) = 0)$ then

$$\frac{u_1(x)}{u_2(x)} = -\frac{a_1}{a_2}$$

It shows that this ratio is the same for all conjugate points. This is the way obtaining the conjugate points. We now give a nice way of determining the fundamental solutions u_1 and u_2. Since the function $y(x)$, the solution of the Euler-Lagrange equation is second order ODE then it contains two independent constants of integration $y(x, c_1, c_2)$. It is easy to prove the following Lemma.

Lemma 4. $u_i = \frac{\partial y}{\partial c_i}$, $i = 1, 2$.

Hence the conjugate points are easily determined from the following formula. Let $Y = (\frac{\partial y}{\partial c_1})/(\frac{\partial y}{\partial c_2})$ then

$$Y(x) = Y(a)$$

Let A' be the first conjugate point to A when moving on the extremal curve $y(x)$ in the direction from $A = (a, y(a))$ to $B = (b, y(b))$. There are three possibilities

(i) B lies between A and A',
(ii) B coincides with A',
(iii) B lies beyond A'.

In all three cases $u(x)$ vanishes at A, but in case (i) it can not vanish again at the point B, in case (ii) it vanishes again at B, and in case (iii) it vanishes again at some point of the arc AB lying between A and B. In case (i) we have $u(a) = h(a) = 0$ but $u(b) \neq 0$, $h(b) = 0$. Hence $u(x)$ can not be proportional to $h(x)$ at all points of the extremal arc AB. Therefore we must have $(h' - h\frac{u'}{u})^2 > 0$ at all points of AB , except, possibly, at finite number of points where $h(x)$ and $h'(x)$ vanish simultaneously. Then we have the following theorem *Jacobi test*.

Theorem 5. *Let $y = y(x)$ be the curve connecting the points A and B for which the functional $J(y) = \int_a^b L(x, y, y')dx$ takes its exremum value. Let A and A' be the conjugate points on this curve. If* **(i)** *B lies between A and A' and* **(ii)** *L_{11} has constant sign for all points on the arc AB, then $J(y)$ is a minimum (maximum) when $L_{11} > 0$ $(L_{11} < 0)$*

For all the other cases we need higher variations for extremum tests.
